Refusal, avoidance, and postponement of needed treatments happen frequently in health care systems.\textsuperscript{1–4} The patient’s low engagement in care has been attributed to several socio-demographic and contextual factors including the patient’s age, sex, ethnic group status, personality, medical and mental conditions, type and complexity of care, as well as the type of health care setting.\textsuperscript{5–10} Clinical diagnostic procedures, treatments and care settings with fear-evoking characteristics such as imaging rooms, CT scan machines, blood tests, colonoscopy and surgical procedures, and dental clinics are good examples of environments and contexts that can cause medical and dental anxiety or phobia. Treatment phobia shapes individuals’ disruptive behaviour patterns and leads to preoperative anxiety, which is associated with state treatment anxiety and increased postoperative pain.\textsuperscript{11,12}

Improved anxiety regulation and pain control is critical for maintaining health and well-being, empowerment of positive health care behaviours, and optimal care management.\textsuperscript{13,14} Music has been used in several clinical settings to engage patients in self-regulation of anxiety and pain control.\textsuperscript{15} Growing clinical evidence attests that music exerts anxiolytic effects on patients undergoing invasive medical procedures or cancer experience. It may be used as an adjunctive intervention in many conditions such as musculoskeletal disease, cardiovascular disease, and dementia, by influencing the activity of brain/emotion networks, initiating corresponding physiological responses, and contributing to psychological well-being and engagement in self-care activities.\textsuperscript{15–22}

Although the underlying mechanisms through which music produces its impact are not yet completely understood, cognitive and emotional pathways have been proposed as key mediators. Activities that distract attention help attenuate pain or decrease anxiety.\textsuperscript{23–25} Recent neuroscience research has also demonstrated the power of music to induce pleasure and modulate arousal.\textsuperscript{26–29} Experimental research indicates that the subjective pleasantness of music contributes to its analgesic effects,\textsuperscript{30} consistent with neuroimaging studies showing how positive emotions reduce the brain response to acute pain.\textsuperscript{31} The neural impulses produced by music affect the autonomic nervous system, modulate activity in brainstem structures, and initiate the reflexive brainstem and endocrine system responses, which provoke changes in blood pressure, heart rate, and anxiety level by releasing a series of hormones such as corticotropin-releasing hormone and norepinephrine.\textsuperscript{32,33} Pleasant emotions induced by music further inhibit pain-related reflex responses of the spinal cord.\textsuperscript{34} The magnitude and kind of response to music depend on several factors related to the individual’s characteristics, the type of music, and preferenc-
Culturally adapted musical intervention for patient-centred health care

For planning future research activities and projects on the use of music in clinical setting. Accordingly, a closed-invitation workshop was conducted in May 2017 in Montreal at the International Laboratory for Brain, Music and Sound Research (BRAMS) affiliated with the University of Montreal and McGill University.

During the one-day workshop, several researchers and experts in fundamental, translational, and clinical research in the fields of music, pain, neuropsychology, mental health, and oral health from Canadian and international universities and research institutions were invited to discuss patient-centred health care innovations with clinicians, community, and health care industry representatives, and end-knowledge users. The development and implementation of culturally adapted music interventions in clinical care was the main theme of this workshop, with three specific objectives:

I. Consolidation of research partnership with patients, clinicians, researchers, policy makers, and e-health industry engaged in the fields of dentistry and mental health.
II. Knowledge exchange and dissemination on the effect of music on emotion and pain control, from basic science to e-health innovation.
III. Planning for the submission of grant proposals.

Dr. Pierre Blanchet, the vice-dean of research at the faculty of dental medicine at the University of Montreal, opened the workshop by putting emphasis on the importance of clinical interdisciplinary and intersectoral research. The three organizers of the workshop, Drs. Elham Emami, Nathalie Gosselin, and Pierre Rainville, facilitated the workshop oral presentations and discussion groups. The workshop oral presenters were invited to present the five subthemes of the workshop displaying the interdisciplinary and intersectorial nature of the workshop:

I. Patient-centred care: Empowering patients’ own-care engagement
II. Anxiety and pain: Clinical and research perspectives
III. Brain/emotion networks and music: Mechanism of interactions
IV. Music intervention: From bench to clinic and e-health innovation
V. Cultural context of music intervention

The subtheme cultural context of music included an overview of Indigenous music and its impact on the conceptualization of health and healing.
Some key points of the presentations are presented here with their references:

- Low engagement in care includes missing appointments, which is a current problem for private dental health care sectors, as well as for those organizations that offer free or low-cost dental services such as Indigenous communities’ oral health care centres and dental faculties.47
- Past negative dental experiences related to injection needles, drill noises, and sitting in a dental chair are associated with dental phobia.48 Since individuals with dental anxiety and phobia are less likely to seek dental care, they are more prone to have poorer oral health.49,50
- Anxiety is a physiological emotional response toward an anticipated threat and is the result of the integrated activity of affect-generating brain systems and emotional effector systems.31
- Dental and medical anxiety and phobia can lead to sleep disturbance, impaired life-activities, and psychological difficulties.52
- Addressing dental and medical anxiety and phobia control has public health implications but needs an innovative, personalized, and culturally adapted behavioural approach.
- Music interventions are a non-pharmaceutical, non-invasive, and inexpensive approach, which can be used to prevent the side effects of medication used for pain and anxiety control such as sleep disturbance, impaired life activities, and psychological difficulties56. Music interventions modify the state of consciousness of the patient and produce a sedative effect while enhancing communication between clinicians and patients in non-traditional ways.
- Music interventions should be tailored based on individuals’ preferences, taking into account the cultural dimension of pleasant music that could potentially enhance activation of the reward system.38-40, 57
- The translation of innovative patient-centred and culturally adapted interventions into practice requires robust, high-quality interdisciplinary and intersectoral research within a real setting, where we can expect a high magnitude of “intervention effects”14, 58-60.

Interactive discussions were brought up after each presentation, which was followed by round-table discussions reflecting on research objectives, design, outcomes, and measures of a clinical trial to test the effect of culturally adapted music on patients’ anxiety and pain. Dental care has been chosen as a model for a stressful care setting, with the long-term objective of adapting the intervention for other clinical settings where the patients may experience pain, anxiety, and treatment phobia.

Workshop short-term outcomes

Overall, participants gave positive evaluations of the workshop and expressed a successful achievement of its main objectives. The workshop was followed by a musical intervention training activity in late August, for dental clinicians participating in the future research project. A start-up fund from the faculty of dental medicine at the University of Montreal has been secured to run a pilot project in 2018–2019. The research team are presently working on a number of research proposals to expand the pilot project and to conduct a demonstration project with an expansion to other health care disciplines.

THE AUTHORS

Dr. Emami is a professor in the faculty of dental medicine, school of public health and Institut de recherche en santé publique de l’Université de Montréal (IRSPUM), University of Montreal. She is also an adjunct professor at McGill University, Montreal, Canada

Dr. Gosselin, is a clinical neuropsychologist and associate professor, department of psychology at the University of Montreal, and International Laboratory on Brain, Music and Sound Research (BRAMS), Centre for Research on Brain, Language and Music (CERB). Montreal, Canada

Dr. Rainville, is a professor in the faculty of dental medicine, research centre, Institut Universitaire de Gériatrie de Montréal (IUGM), University of Montreal, Montreal, Canada.

Dr. Durand is an associate professor in the faculty of dental medicine, University of Montreal.

Acknowledgments

Financial support from the Canadian Institutes of Health Research (Planning and Dissemination Grant – Institute Community Support, Musculoskeletal Health and Arthritis Institute) is gratefully acknowledged. We would like to thank all speakers and workshop participants, including the undergraduate and postgraduate students, for their dynamic participation in the workshop. Special thanks to Roxane Campeau for her impressive presentation on Indigenous music as well as Morgane Bertacco and Teresa Gormes for their help and efforts during this workshop.
We are thankful to Dr. Stéphane Guétin at the Clinical Psychology and Psychopathology Laboratory University Paris S-René Descartes; Mme Jill Torrie at Cree Board of Health and Social Services of James Bay; Drs. René Voyer, Thomas Nguyen, and Pierre Boudrias at the faculty of dental medicine at University of Montreal; Drs. Faleh Tamimi and Nicholas Makkoul at McGill University faculty of dentistry; and Dr. Linda Boiij at Concordia University for their active collaboration in various phases of this workshop from funding to building interdisciplinary research project.
