RÉSUMÉ

Les procédures standards pour tester la présence de racines unitaires aux fréquences saisonnières sont basées sur une représentation invariante ARIMA. Une classe alternative de processus est celle des modèles à variations périodiques des paramètres. Dans cette étude, nous présentons des tests de racines unitaires qui prennent explicitement en compte une structure périodique. Les distributions asymptotiques sont dérivées. Une étude Monte Carlo démontre les avantages de nos tests par rapport aux procédures standards.

Mots-clés:

modèles périodiques, racines unitaires saisonnières.

ABSTRACT

The standard testing procedures for seasonal unit roots developed so far have been based mainly on time invariant ARMA processes with AR polynomials involving seasonal differencing. One attractive alternative is to employ periodic ARMA models in which the coefficients are allowed to vary with the season. In this paper, we present convenient procedures for testing for the presence of unit roots at the zero and seasonal frequencies in periodic time series. The limiting distributions of these statistics are derived and tabulated. Simulation evidence illustrates the advantages of allowing for periodicity in this context when it is present. The tests are illustrated via applications to macroeconomic and ozone level data.

Key words:

periodic models, seasonal unit roots.

1. INTRODUCTION

Two types of model specifications are most often considered for seasonal time One consists of time-invariant autoregressive integrated moving average (ARIMA) processes with AR polynomials involving first and/or seasonal differencing. This class of models, popularized through the work of Box and Jenkins (1976), has become standard textbook material.1 A celebrated example of this class is the so-called airline model named after the passenger data set to which it was originally fitted. The second class has gained considerable interest in recent years, though it is still a distant second in terms of applications. Its original source of inspiration was the work of Gladysev (1961) on periodic autocorrelations and was later refined by Tiao and Grupe (1980). The models are usually referred to as periodic ARIMA models because they are characterized by deterministic seasonal variation in the parameters. Several papers explored the estimation and testing of periodic models, including Jones and Brelsford (1967), Pagano (1978), Troutman (1979), Tiao and Guttman (1980), Andël (1983), Cipra (1983), Vecchia (1985a), Andël (1987), Andël (1989), Hurd and Gerr (1991), Lütkepohl (1991), Sakaï (1991), Vecchia and Ballerini (1991), Anderson and Vecchia (1993), Boswijk and Franses (1993), Ghysels and Hall (1993), McLeod (1993), Bentarzi and Hallin (1994), Franses (1994), among others. In addition, these models found successful applications in economics, environmental studies, hydrology and meteorology, see inter alia., Bhuiya (1971), Noakes et al. (1985), Vecchia (1985b), Vecchia et al. (1985), Osborn (1988), Birchenhall et al. (1989), Jiménez et al. (1989), Osborn and Smith (1989), Todd (1990), Ghysels and Hall (1992),

To date, tests of whether first or seasonal differencing is appropriate have been developed within the framework of time invariant ARIMA models; see inter alia, Hasza and Fuller (1982), Dickey, Hasza and Fuller (1984), Hylleberg et al. (1990). However, seasonal unit roots characterize the nonstationarity of periodic patterns in time series and so it is natural to test for these roots in the context of periodic models. In this paper, we propose a number of statistics which allow a researcher to test for the presence of zero and seasonal frequency unit roots in periodic AR models. We derive and tabulate the limiting distributions of our statistics. Simulation evidence

Besides textbooks, it is also worth mentioning survey papers on the subject such as Bell and Hillmer (1984) or Ghysels (1994). While the majority of the literature focuses on univariate models, some authors have studied multivariate extensions. Recent examples include Lee (1993) and Ahn and Reinsel (1994).

demonstrates that there can be considerable gains in power from taking account of the presence of periodicity when it is present.

An outline of the paper is as follows: in section 2, we examine the issue of testing for the presence of certain roots in the autoregressive polynomial of a periodic time series. Section 3 extends this analysis by introducing joint tests for the presence of these roots; one of these tests examines whether seasonal differencing is appropriate. Section 4 contains the results from a simulation study and an investigation of two empirical examples. All proofs are relegated to a mathematical appendix.

2. TESING FOR THE PRESENCE OF INDIVIDUAL ROOTS

Let the seasonal differencing operator to be defined as $\Delta_s = (1 - B^s)$ where B is the backshift operator and S is the seasonal sampling frequency. In the cases of annual, biannual, quarterly and monthly data, S takes the values 1, 2, 4, and 12, respectively. Following Box and Jenkins (1976), the seasonal differencing operator is applied to a series because it is believed to render a series stationary around, potentially, some deterministic level. However, although this transformation is a very natural choice, it actually amounts to an assumption about the values of roots of the autoregressive polynomial. For example:

$$\Delta = 1 - B$$

$$\Delta_2 = \Delta(1 + B)$$

$$\Delta_4 = \Delta_2 (1 + B^2)$$

$$\Delta_{12} = \Delta_4 (1 + B + B^2) (1 - B + B^2) (1 + \sqrt{3}B + B^2) (1 - \sqrt{3}B + B^2).$$

Therefore, as is well-known, the use of Δ corresponds to the assumption of a real autoregressive root of 1; Δ_2 corresponds to real roots of \pm 1; Δ_4 contains these two real roots plus the complex roots \pm 1; Δ_{12} contains the roots of Δ_4 plus four additional pairs of complex conjugate roots. These roots imply different types of behavior. For example, the root of -1 corresponds to a component exhibiting two cycles per year and the roots of \pm 1 correspond to a component exhibiting four cycles per year. From this perspective, it may be of interest to test for the presence of these individual effects. In this section, we develop test procedures that allow this in the context of periodic

time series. In the next section, we extend this to joint tests which allow one, for instance, to test whether seasonal differencing is appropriate.

However, first we must address a matter of notation. In our presentation, it is necessary to distinguish the periodic function which determines a parameter value in a given period and the arguments of this function. All parameters are represented by "lower case" greek letters and we use ξ_1 , say, to denote the periodic function $\sum_{s=1}^{S} D_{st} \xi_s$ where D_{st} is an indicator variable which takes the value 1 if $s = t \mod S$. Similarly, ξ_{jt} denotes $\sum_{s=1}^{S} D_{st} \xi_{sj}$. It will always be clear from the context whether we refer to the function ξ_t or to the values it takes $\{\xi_s; s = 1, ..., S\}$.

It is most convenient to introduce the tests in the context of a zero mean periodic autoregressive model and then extend the results to models with an intercept and time trend. Consider the model:

$$y_{i} = \sum_{j=1}^{p} \rho_{ji} y_{i-j} + u_{i}.$$
 (2.1)

Without loss of generality, we assume t = (n - 1)S + s for n = 1, 2, ..., N and s = 1, 2, ..., S; this gives a sample of size T = NS. To facilitate our analysis, we impose the following condition:

C.1: $\{u_t\}$ is a sequence of i.i.d. random variables with $E(u_t) = 0$, $E(u_t^2) = \sigma^2$ and $\sup_t E[u_t]^{\gamma} < \infty$ for some $\gamma > 2$.

Our inference is based on the regression models given in equations (2.2) and (2.3). First, consider the model:

$$y_{t} = \alpha_{t} y_{t-1} + \sum_{j=1}^{p-1} \theta_{jt} z_{1,t-j}^{\phi} + u_{t}$$
 (2.2)

where $z_{1,t}^{\phi} = (1 - \phi B)y_t$. If y_t possesses a unit root at the zero frequency, then it has the representation in (2.2) with $\alpha_s = 1$, s = 1, 2, ..., S and $\phi = 1$. If y_t has the root -1,

then it has the representation in (2.2) with $\alpha_s = -1$, s = 1, 2, ..., S, and $\phi = -1$. Therefore, to test for the presence of either of these roots, one can estimate (2.2) with $\phi = c$ and test whether $\alpha_s = c$ for $c = \pm 1$. These two null hypotheses can be written compactly as:

$$H_0^R(\phi)$$
: $\alpha_s = \phi$, $s = 1, 2, ..., S$

for $\phi = -1$ or 1; here the R superscript stands for "real" roots. The alternative denoted $H_1^R(\phi)$, is that at least one $\alpha_s \neq \phi$.

We now turn to inference about the complex roots. Consider the regression model:

$$y_{t} = \gamma_{1t} (-y_{t-1}) + \gamma_{2t} y_{t-2} + \sum_{j=1}^{p-2} \theta_{jt} z_{2,t-j}^{\phi} + u_{t}$$
 (2.3)

where $z_{2,t}^{\phi} = (1 - \phi B + B^2)y_t$. Note that for notational convenience, the coefficients on $z_{1,t-j}^{\phi}$ and $z_{2,t-j}^{\phi}$ in equations (2.2) and (2.3) are both denoted θ_{jt} ; however, the values taken by θ_{jt} are different in each case. This will not cause any ambiguity since none of the tests explicitly depend on θ_{jt} . If y_t possesses the complex conjugate pair of roots associated with $(1 - \phi z + z^2)$, then it has the representation in (2.3) with $\gamma_{1s} = \phi$, $\gamma_{2s} = 1$ for s = 1, 2, ..., S. Consequently, one can test for the presence of these roots by estimating (2.3) with the appropriate choice of ϕ in $z_{2,t}^{\phi}$ and testing if $\gamma_{1s} = \phi$, $\gamma_{2s} = 1$. This null hypothesis can be written compactly as:

$$H_0^C(\phi)$$
: $\gamma_{1s} = \phi$, $\gamma_{2s} = 1$; $s = 1, 2, ..., S$

for $\phi = 0, \pm 1, \pm \sqrt{3}$. Here, the C superscript stands for "complex" roots. The alternative, denoted $H_1^C(\phi)$, is that at least one $\gamma_{1s} \neq \phi$ or one $\gamma_{2s} \neq 1$ in which case the series does not possess the roots associated with $(1 - \phi z + z^2)$.

All our inference procedures are based on the Wald statistic for testing linear restrictions on the parameters of a linear regression model estimated by ordinary

least squares. The generic formula for the statistic is as follows. Suppose the regression model is:

$$y = X\beta + u$$

where y, u are $T \times 1$ vectors of observations on the dependent variable and error respectively; X is the $T \times k$ matrix of observations on the regressors. The Wald statistic for testing $R\beta = r$ is:

$$W = (R\hat{\beta} - r)' [R(X' X)^{-1} R']^{-1} (R\hat{\beta} - r) / \hat{\sigma}^2$$
(2.4)

where $\hat{\beta} = (X' X)^{-1} X' y$ and $\hat{\sigma}^2 = y'[1 - X(X' X)^{-1} X']y / T$.

Let $W_S^R(\phi)$ denote the Wald statistic for testing $H_0^R(\phi)$ based on (2.2) and let $W_S^C(0)$ denote the Wald statistic for testing $H_0^C(\phi)$ based on (2.3). To present the limiting distribution of these statistics, we must introduce the following relation: let $B_S(r)$ denote an S-dimensional standard Brownian motion, G(r) denote the (4 × 1) standard Brownian motion given by:

$$G(r) = [S^{-1/2} G_1(r), S^{-1/2} G_2(r), (S/2)^{-1/2} G_3(r), (S/2)^{-1/2} G_4(r)]^{-1/2}$$

where
$$G_1(r) = \sum_{s=1}^{S} B_{S_s}(r)$$
, $G_2(r) = \sum_{s=1}^{S} (-1)^s B_{S_s}(r)$, $G_3(r) = \sum_{s=1}^{S/2} (-1)^{s-1} B_{S_j(s)}$

j(s) = 2s-1, $G_4(r) = \sum_{s=1}^{S/2} (-1)^s B_{Sk(s)}$, k(s) = 2s. The distributions of these test statistics are as follows:

THEOREM 2.1: Let y_t be generated by (2.1) and assume C.1 and A.1 defined in the appendix hold, then: (i) under $H_0^R(\phi)$, $W_S^R(\phi) \Rightarrow \psi_S^R$, $\phi \pm 1$; (ii) under $H_0^C(\phi)$, $W_S^C(\phi) \Rightarrow \psi_S^C$, $\phi = 1, \pm 1, \pm \sqrt{3}$

where
$$\psi_S^R = \sum_{s=1}^S |\int_0^1 G_1(r) dB_{Ss}|^2 / \int_0^1 G_1(r)^2 dr$$
,
$$\psi_S^C = \text{trace } \{ \int_0^1 G_{34}(r)' dG(r) |\int_0^1 G_{34}(r) G_{34}(r)' dr \}^{-1} \int_0^1 G_{34}(r) dG(r)' \},$$

and $G_{34}(r)$ is the (2 × 1) subvector of G(r) containing its 3rd and 4th elements.

The limiting distributions only depend on the known parameter S. Percentiles are presented in Table 2.1 for $S = 4,12.^2$ The table covers the case without intercept and linear trend. The intercept case, as well as intercept plus trend cases, are discussed next.

In many cases, it may indeed be appropriate to include an intercept or time trend in the model. Accordingly, consider the models:

$$y_{t} = \alpha_{t} y_{t-1} + \mu_{t} + \sum_{j=1}^{p-1} \theta_{jt} z_{1,t-j}^{\phi} + u_{t},$$
 (2.5)

$$y_{i} = \alpha_{i} y_{i+1} + \mu_{i} + \beta_{i}(n - N/2) + \sum_{j=1}^{p-1} \theta_{ji} z_{1,i-j}^{\phi} + u_{i}$$
 (2.6)

$$y_{t} = \gamma_{1t}(-y_{t-1}) + \gamma_{2t} y_{t-2} + \mu_{t} + \sum_{j=1}^{p-2} \theta_{jt} z_{2,t-j}^{\phi} + u_{t}.$$
 (2.7)

$$y_{t} = \gamma_{1t}(-y_{t-1}) + \gamma_{2t} y_{t-2} + \mu_{t} + \beta_{t}(n - N/2) + \sum_{j=1}^{p-2} \theta_{jt} z_{2,t-j}^{\phi} + u_{t}.$$
 (2.8)

Let $W_{S\mu}^R(\phi)$, $W_{S\tau}^R(\phi)$ be the Wald statistics for testing $H_0^R(\phi)$ based on (2.5) and (2.6), respectively. Likewise, let $W_{S\mu}^C(\phi)$, $W_{S\tau}^C(\phi)$ be the Wald statistics for testing $H_0^C(\phi)$ based on (2.7) and (2.8), respectively. The limiting distributions of these statistics are as follows:

² All computations were performed using the RATS, Version 4.01, package of ESTIMA, Inc. To calculate the critical values, we used 10,000 iterations. For S = 12 and N = 20, we only report the case of no intercept and trend since the other cases yielded essentially similar critical values.

THEOREM 2.2: Let y_i be generated by (2.1) assume C.1 and assumption A.1 defined in the appendix hold, then: (i) under $H_0^R(\phi)$, $W_{S\mu}^R(\phi) \Rightarrow \psi_{S\mu}^R$, $W_{S\tau}^R(\phi) \Rightarrow \psi_{S\tau}^R$ for $\phi = \pm 1$; (ii) under $H_0^C(\phi)$: $W_{S\mu}^C(\phi) \Rightarrow \psi_{S\mu}^C$, $W_{S\tau}^C(\phi) \Rightarrow \psi_{S\tau}^C$ for $\phi = 0, \pm 1, \pm \sqrt{3}$.

For brevity, these limiting distributions are defined in the appendix; again, they only depend on S and percentiles are presented in Table 2.1 as noted before.

Finally, we observe that the statistics $W_S^R(\phi)$ are asymptotically equivalent to the sum over s=1,2,...,S of the squared t-statistics for H_0 : $\alpha_s=\phi$ from the appropriate regression model. This provides a convenient method of calculation from standard regression computer output.

3. TESTING FOR SEASONAL DIFFERENCING

We now turn to the question of testing the hypothesis that seasonal differencing would yield a stationary series. From the previous section, it is clear that this amounts to testing a joint hypothesis about the roots of the autoregressive polynomial. To illustrate the structure of these joint tests, we concentrate on the case where S = 4. The procedures easily extend to the case where S = 12 and this is discussed in the appendix. Let $y_{11} = (1 + B + B^2 + B^3)y_1$, $y_{21} = -(1 - B + B^2 - B^3)y_1$, $y_{31} = -(1 + B^2)y_1$, $z_1^4 = (1 - B^4)y_1$, and consider the regression model:

$$z_{t}^{4} = \pi_{1t} y_{1t-1} + \pi_{2t} y_{2t-1} + \pi_{3t} y_{3t-1} + \pi_{4t} y_{3t-2} + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{4} + u_{t}. \quad (3.1)$$

In the context of aperiodic time series, Hylleberg et al. (1990) showed that various parameter restrictions among the π coefficients correspond to the existence of the roots discussed in the previous section. Ghysels, Lee and Noh (1994) showed that this procedure can be extended to test for seasonal differencing. In this section, we generalize this framework to periodic time series.

If y_i possesses all the roots ± 1 , $\pm i$, then it has the representation in (3.1) with $\pi_{is} = 0$, i, s = 1, 2, 3, 4. This corresponds to the case where seasonal differencing yields stationarity.

We denote this null hypothesis by:

$$H_0^A(4)$$
: $\pi_{is} = 0$ for all i, s = 1, 2, ..., 4

where the A superscript stands for "all roots" and the 4 refers to the quarterly data. The alternative, $H_1^A(4)$ is that at least one $\pi_{is} \neq 0$.

A related hypothesis is whether all the "seasonal roots" -1, $\pm i$ are present. If this is the case, then y_t has the representation in (3.1) with $\pi_{is} = 0$ for i = 2, 3, 4, s = 1, ..., 4. Note that this representation is valid irrespective of whether y_t possesses the root 1, i.e., a unit root at the zero frequency. We denote this null hypothesis by:

$$H_0^S(4)$$
: $\pi_{is} = 0$ $i = 2, 3, 4, s = 1, 2, ..., 4$

where the S superscript stands for "seasonal roots"; again the alternative is that $\pi_{is} \neq 0$ for at least one i > 1 and one s.

Let W_S^A , W_S^S with S=4 denote the Wald statistics for testing $H_0^A(4)$ and $H_0^S(4)$, respectively. The limiting distributions of these statistics are derived in the appendix. The notation for these distributions is presented in Table 3.1 and the percentiles are given in Table 3.2. One may also wish to include an intercept or a time trend in the model and so estimate either:

$$z_{t}^{4} = \sum_{i=1}^{3} \pi_{it} y_{i,t-1} + \pi_{4t} y_{3,t-2} + \mu_{t} + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{4} + u_{t}$$
(3.2)

or

$$z_{t}^{4} = \sum_{i=1}^{3} \pi_{it} y_{i,t-1} + \pi_{4t} y_{3,t-2} + \mu_{t} + \beta_{t} (n - N/2) + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{4} + u_{t}. (3.3)$$

The presence of the deterministic terms in (3.2) and (3.3) does not alter the arguments above, although it does change the limiting distributions. Let $W_{S\mu}^A$, $W_{S\tau}^A$ with S=4 be the Wald statistics for testing $H_0^A(4)$ based on (3.2) and (3.3), respectively. Similarly, let $W_{S\mu}^S$, $W_{S\tau}^S$ be the Wald statistics for testing $H_0^A(4)$ based on (3.2) and (3.3). The limiting distributions are summarized in Table 3.1 and described in the appendix.

For the case where S=12, one must modify the regression models in the fashion shown in the appendix. The notation for these tests is analogous to the quarterly case:

$$H_0^A(12)$$
: $\Delta_{12}^- y_i^-$ is stationary

$$H_0^S(12)$$
: y_i possesses the roots of Δ_{12} / Δ ,

and W_{12}^A is the Wald test of $H_0^A(12)$ based on the monthly analogs of (3.1) (equation (A.21) in the appendix), etc. The limiting distributions are summarized in Table 3.1 and the percentiles presented in Table 3.2.

We conclude this section by noting that all the limiting distributions presented in this section are free of nuisance parameters.

Table 3.1: Test Statistics and Their Limiting Distributions

Null hypothesis	Regression model	Limiting distributions of Wald statistics
H ₀ ^A (4)	(3.1)	v ^A
	(3.2)	Ψ ^A _{4μ}

4. SIMULATION EVIDENCE OF FINITE SAMPLE PROPERTIES AND EMPIRICAL APPLICATIONS

In this final section, we report results of a Monte Carlo study of the finite sample properties of the statistics presented in the previous two sections and then two empirical applications.

The design of the experiments was based on the following data generating process:

$$(1 - a_s B) (1 + B) 1 - a_s B^2) y_t = u_t$$
 (4.1)

where u_t is i.i.d. N(0,1) and t = (n-1) 4 + s. Notice, we focus exclusively on a quarterly model where periodic behavior may appear at the zero and seasonal frequencies; the values of a are given in Table 4.1. It should be noted that a was selected to control both types of roots simultaneously in order to keep the number of cases limited. A total of six test statistics were considered, three of which are commonly used and do not explicitly exploit the periodic features in the DGP, and three statistics introduced in sections 2 and 3. The first set of statistics includes: (a) the Dickey-Puller t statistics, denoted DF; (b) the joint test proposed by Ghysels, Lee and Noh (1994) for the presence of unit roots at all the seasonal frequencies, denoted GLN; and (c) the joint test for the (1 - B4) operator proposed by Hylleberg et al. (1990), denoted HEGY. In each case, the auxiliary regression models did not include a trend nor seasonal dummies or a constant. The sample size selected was 20 years, or 80 observations. The second set of three statistics includes: (a) the $W_4^R(1)$ statistic described in Theorem 2.1, (b) the W_4^S statistic, and (c) the W_4^A statistic both appearing in section 3. Hence, the first and second set of test statistics cover similar hypotheses regarding the presence unit roots at the zero and seasonal frequencies.

Table 4.1 reports simulation results based on 10,000 Monte Carlo simulation using the RNDN function of the GAUSS package. The top line of Table 4.1 shows that none of the statistics show any noticable size distortion. The next line in Table 4.1 stresses an interesting feature as it relates to a case where the product of the α_s coefficients equals one, yet with the α_s differing dramatically. Let us first focus on the first set of three statistics. First, we notice that the DF statistic has its power equal to its size while the two joint statistics GLN and HEGY reject the null outright.

Table 4.1: Monte Carlo Design and Results

Notes: DF: Dickey-Fuller t statistics; GLN: statistics for roots at seasonal frequencies in Gbysels, Lee and Noh: HEGY: statistic for assonal differencing in Hylleberg et al. All three remaining statistics are defined in sections 2 and 3. All computations involved 10,000 iterations. Sample size is 20 years; DGP is described by equation (4.1).

This first case stresses the advantage of taking periodicity into account as is done in the second block of three statistics. Indeed, with the product of the a coefficients equal to one, the DF statistic is "tricked" by the fact that, on average across all four seasons, there is a unit root. The GLN and HEGY statistics are not affected by the fact that The last a unit 100. The obstance $a_s = 1$, instead they would be affected by for instance $a_s = 1$. Looking at $a_s = 1$, instead they would be affected by for instance $a_s = 1$. the three statistics together, DF, GLN and HEGY, one would conclude in most circumstances that one should take a first difference of the data. Instead, the periodic tests, $W_4^R(1)$, W_4^S and W_4^A , show good power properties in rejecting unit root behavior at all the frequencies. The next case is also particularly interesting. The product of the a_s coefficients now equals -1, because all but one coefficient equal 1.0 and the fourth is -1. Let us first discuss what impact this has on the data generating process appearing in (4.1). Since the polynomial on the left-hand side equals $(1 - a_s B) (1 + B)$ $(1 + a_s B^2)$, one finds for the three seasons $(1 - B)(1 + B)(1 + B^2)$ while for the fourth season, the polynomial equals (1 + B)³ (1 - B). Hence, in each of the four seasons, the polynomial contains the (1 - B) unit root. Yet, looking at the results in Table 4.1, we notice that the DF statistic strongly rejects the zero frequency unit root hypothesis, simply because $\prod_{s=1}^{4} a_s = -1$ and no unit root behavior is detected on average. In contrast, the W4(1) statistic correctly identifies the zero frequency unit root while the W_4^S and W_4^A also strongly reject the presence of unit roots at all seasonal frequencies. The final case appearing in Table 4.1 stresses the fact that the nonperiodic tests may be powerful, nevertheless. Here, the product of the a coefficients equals 0.64 which is far from the unit circle yet two coefficients equal to 1.0 while the two others equal 0.8. Comparing DF, GLN and HEGY with the periodic tests reveals that the former group of tests is more powerful in these circumstances. Such a DGP is probably uncommon in practice yet it is useful here to point out situations where traditional tests are more powerful.

To conclude, we consider some empirical applications which draw upon Osborn (1988), Osborn and Smith (1989) and Bloomfield, Hurd and Lund (1994). The former two applied periodic models to economic time series while the latter studied stratospheric ozone data with similar models. Using the data from the original articles, we apply our tests as well as the three nonperiodic tests considered in the Monte Carlo simulations. Osborn and Smith (1989) examine U.K. quarterly consumers' expenditures

and assess the benefits that may accrue from the use of periodic models. Nondurable consumer goods are available in a number of categories: alcoholic drink and tobacco: clothing, footwear; and energy products. To this set of series, we also add the total of nondurable consumption as well as disposable income and prices [the latter are studied in Osborn (1988)]. All data cover a sample from 1955:1 until 1984:2. The results appearing in the top panel, covering the quarterly data series, underline the benefits of allowing for periodicity in testing for unit roots in seasonal data. With the GLN and HEGY test statistics, one would accept the presence of unit roots at seasonal frequencies in several cases. In contrast, for none of the eight series is there supporting evidence of unit roots at seasonal frequencies according to the W_4^S and W_4^A statistics. For the zero frequency unit root, the results are more mixed, often finding agreement between the DF and $W_c^R(1)$ statistics.

Table 4.2: Empirical Results of Tests for Unit Roots in Periodic Time Series

Data	DF	GLN	HEGY	$W_{S}^{R}(1)$	ws	w _S ^A

Ozone Data	5.81**	31.81**	31.93**	20.06	985.88**	1007.4**

Notes: For description test statistics, see Table 4.1. The quarterly data are taken from Osborn (1988) and Osborn and Smith (1989). The monthly data are from Bloomfield,

A second and final data set contains 50 years of monthly observations of stratospheric ozone data from Arosa, Switzerland. Bloomfield, Hurd and Lund show that the correlation structure of such data displays strong periodic features and suggests an ARMA model with periodically varying coefficients to fit the data. According to the results appearing in Table 4.2, we find one significant difference between the left and right panels, respectively, covering tests based on nonperiodic and periodic models. Indeed, we find that the zero frequency unit root hypothesis cannot be rejected with the $W_S^R(1)$ test. This appears to contradict the evidence based on a standard DF test.

APPENDIX A

We first present some useful notations and results which will be used below to develop the asymptotic distribution theory for the statistics proposed in the text.

Define:

$$w_{kn} = \sum_{i=1}^{n} \sum_{s=1}^{S} e_{ki}(s) \quad \text{for } k = 1, 2, 3, 4.$$
 (A.1)

where

$$\begin{split} e_{1i}(s) &= u_{(i-1) \ S+s}, \qquad e_{2i}(s) = (-1)^s \ u_{(i-1) \ S+s}, \\ e_{3i}(s) &= \sin \frac{\pi}{2} \left[(i-1) \ S+s \right] u_{(i-1) \ S+s} \ ^{and} \\ e_{4i}(s) &= \cos \frac{\pi}{2} \left[(i-1) \ S+s \right] u_{(i-1) \ S+s}. \end{split}$$

Note that (A.1) implies that:

$$w_{1n} = \sum_{t=1}^{nS} u_{t}, \quad w_{2n} = \sum_{t=1}^{nS} (-1)^{t} u_{t}$$

$$w_{3n} = \sum_{t=1}^{nS} \sin(\frac{\pi}{2}t) u_{t}, \text{ and } w_{4n} = \sum_{t=1}^{nS} \cos(\frac{\pi}{2}t) u_{t}.$$

Note also that:

$$w_{kn} = w_{k,n-1} + v_{kn} = \sum_{i=1}^{n} v_{ki}$$
 (A.2)

where
$$v_{kn} = \sum_{s=1}^{S} e_{kn}(s)$$
.

Let U_{kn} denote $S \times 1$ vectors such that:

$$U_{kn} = [e_{kn}(1), e_{kn}(2), ..., e_{kn}(S)]'$$
 for $k = 1, 2, 3, 4$. (A.3)

From Phillips and Durlauf (1986, Theorem 2.1), we have:

$$N^{-1/2} \sum_{n=1}^{\lfloor Nr \rfloor} U_{1n} \rightarrow \sigma B_1(r) \equiv \sigma W(r)$$
(A.4.1)

where $B_1(r) = W(r)$ is an S-dimensional standard Brownian motion with s^{th} element $W_s(r)$. Similarly, we can show that:

$$N^{-1/2} \sum_{n=1}^{[Nr]} U_{2n} - \sigma B_2(r)$$
(A.4.2)

where $B_2(r)$ is an S-dimensional standard Brownian motion with s^{th} element $B_{2s}(r) = (-1)^s$ $W_s(r)$ for s = 1, ..., S.

Noting that:

$$e_{3n}(s) = 0$$
 for $S = 2 k + 2$ and $k = 0, 1, ...$

$$e_{3n}(s) = u_{(n-1)S+s}$$
 for $s = 4 k + 1$

$$e_{3n}(s) = (-1) u_{(n-1)S+s}$$
 for $s = 4 k + 3$

it can be shown that $N^{-1/2} \begin{bmatrix} N r \\ \Sigma \\ n = 1 \end{bmatrix} \cup U_{3n} \rightarrow \sigma B_3(r)$, where

$$B_3(r) = [W_1(r), 0, -W_3(r), 0, ...].$$
 (A.4.3)

From the definition of $e_{4n}(s)$, we can similarly show that $N^{-1/2} \sum_{n=1}^{\lceil Nr \rceil} U_{4n} \to \sigma B_4(r)$, where

$$B_4(r) = [0, -W_2(r), 0, W_4(r), ...].$$
 (A.4.4)

Using (A.2), we have:

$$\mathbf{w}_{kN} = \sum_{n=1}^{N} \mathbf{v}_{kn} = i' \sum_{n=1}^{N} \mathbf{U}_{kn}$$

where i is an S-dimensional vector of ones. From the relations in (A.4), it follows that:

$$N^{-1/2} \sum_{n=1}^{\lceil Nr \rceil} v_{kn} \to \sigma G_k(r)$$
(A.5)

where $G_k(r) = \sum_{j=1}^{S} B_{kj}(r)$. Note here that from the relations (A.4.1)-(A.4.4), we have

$$G_{1}(r) = \sum_{j=1}^{S} W_{j}(r), G_{2}(r) = \sum_{j=1}^{S} (-1)^{i} W_{j}(r), G_{3}(r) = \sum_{j=1}^{S/2} (-1)^{j-1} W_{2j-1}(r), \text{ and } G_{4}(r) = \sum_{j=1}^{S/2} (-1)^{j} W_{2j}(r).$$

Finally, let y_{kt} (k = 1, 2, 3) denote the time series processes generated by the following equations:

$$y_{1t} = y_{1,t-1} + \sum_{j=1}^{p-1} \theta_{tj} z_{1,t-j}^{1} + u_{t}$$
(A.6.1)

$$y_{2i} = -y_{2,i-1} + \sum_{j=1}^{p-1} \theta_{ij} z_{1,i-j}^{-1} + u_{i}$$
 (A.6.2)

$$y_{3i} = -y_{3,i-2} + \sum_{j=1}^{p-2} \theta_{ij} z_{2,i-j}^{0} + u_{i}$$
 (A.6.3)

The processes z_{k1}^{ϕ} are defined following equations (2.2) and (2.3) for k=1 and k=2, respectively. Furthermore, we shall assume the following:

Assumption A.1: The z_{kt}^{ϕ} processes have an infinite order moving average representation

$$C(B)u_{t} = \sum_{i=0}^{\infty} C_{i} u_{t-i}, \text{ where } \sum_{i=0}^{\infty} i |C_{i}| < \infty.$$
(A.7)

The following relations are useful in deriving the asymptotic distribution of the test statistics in Theorem 2.1.

Lemma A.1: As $T \rightarrow \infty$ (and thus $N \rightarrow \infty$), we have:

(i)
$$N^{-2} \sum_{t=1}^{T} D_{st} y_{1,t-1}^{2} \rightarrow C(1)^{2} \sigma^{2} \int_{0}^{1} G_{1}(r)^{2} dr$$
 (A.8.1)

$$N^{-2} \sum_{t=1}^{T} D_{st} y_{2,t-1}^{2} - C(-1)^{2} \sigma^{2} \int_{0}^{1} G_{2}(r)^{2} dr$$
(A.8.2)

$$N^{-2} \sum_{t=1}^{T} D_{st} y_{3,t-1-i}^{2} \rightarrow \left[\sin \frac{\pi}{2} (s-i)\right]^{2} \sigma^{2} \left[C_{R}^{2} \int_{0}^{1} G_{4}(r)^{2} dr\right]$$

$$+ \ C_1^2 \ \int_0^1 G_3(r)^2 \ dr \ - \ C_R \ C_1 \ \int_0^1 G_4(r) \ G_3(r) \ dr \ + \ [\cos \frac{\pi}{2} \ (s \ - \ i)]^2 \ \sigma^2 \ [C_R^2 \ \int_0^1 \ G_3(r)^2 \ dr$$

+
$$C_1^2 \int_0^1 G_4(r)^2 dr + C_R C_1 \int_0^1 G_3(r) G_4(r) dr$$
 for $i = 0, 1$ (A.8.3)

$$N^{-2} \sum_{t=1}^{T} D_{st} y_{3,t-1} y_{3,t-2} \neg (-1)^{s} \sigma^{2} [(C_{R}^{2} - C_{1}^{2}) \int_{0}^{1} G_{3}(r)^{2} G_{4}(r) dr$$

+
$$C_R C_I \int_0^1 (G_3(r)^2 - G_4(r)^2) dr$$
 (A.8.4)

(ii)
$$N^{-1} \sum_{t=1}^{T} D_{st} y_{1,t-1} u_t - C(1) \sigma \int_0^1 G_1(r) dB_{1s}(r)$$
 (A.9.1)

$$N^{-1} \sum_{t=1}^{T} D_{st}(-y_{2,t-1}) u_{t} - C(-1) \sigma \int_{0}^{1} G_{2}(r) dB_{2s}(r)$$
(A.9.2)

$$\begin{split} &N^{-1} \sum_{t=1}^{T} D_{st}(-y_{3,t-1}) u_{t} \rightarrow \cos(\frac{\pi}{2} s) \sigma \left[C_{R} \int_{0}^{1} G_{3}(r) dB_{4s}(r) + C_{1} \int_{0}^{1} G_{4}(r) dB_{4s}(r) \right] \\ &- \sin(\frac{\pi}{2} s) \sigma \left[C_{R} \int_{0}^{1} G_{4}(r) dB_{3s}(r) - C_{1} \int_{0}^{1} G_{3}(r) dB_{3s}(r) \right] \\ &N^{-1} \sum_{t=1}^{T} D_{st}(-y_{3,t-2}) u_{t} \rightarrow \sin(\frac{\pi}{2} s) \sigma \left[C_{R} \int_{0}^{1} G_{3}(r) dB_{3s}(r) + C_{1} \int_{0}^{1} G_{4}(r) dB_{3s}(r) \right] \\ &- \cos(\frac{\pi}{2} s) \sigma \left[C_{R} \int_{0}^{1} G_{4}(r) dB_{4s}(r) - C_{1} \int_{0}^{1} G_{3}(r) dB_{4s}(r) \right] \end{split} \tag{A.9.4}$$

where C_{R} and C_{l} , respectively, denote the real and imaginary part of C(i).

Proof.

(i) When $z_{1t}^1 = y_{1t} - y_{1,t-1}$ has a moving average representation as in (A.7), we can show that [see, e.g., Lee (1992, p. 34)]

$$\mathbf{y}_{1,t} = \begin{bmatrix} \sum_{i=0}^{\infty} \mathbf{C}_i \\ \sum_{j=1}^{\infty} \mathbf{U}_i \end{bmatrix} + \begin{bmatrix} \sum_{j=1}^{\infty} \mathbf{C}_i \\ \sum_{j=0}^{\infty} \mathbf{C}_i \\ \sum_{j=-i+1}^{\infty} \mathbf{U}_i \end{bmatrix} - \begin{bmatrix} \sum_{i=0}^{\infty} \mathbf{C}_i \\ \sum_{j=t-i+1}^{\infty} \mathbf{U}_i \end{bmatrix}$$
(A.10.1)

Using (A.1), it follows that:

$$\begin{split} N^{-2} \sum_{t=1}^{T} D_{st} y_{1,t-1}^{2} &= C(1)^{2} N^{-2} \sum_{t=1}^{T} D_{st} \left[\sum_{t=1}^{t-1} u_{j} \right]^{2} \\ &+ o_{p}(1) = C(1)^{2} N^{-2} \sum_{n=1}^{N} w_{1,n-1} + o_{p}(1). \end{split}$$

The relation (A.8.1) now follows from (A.5) and the continuous mapping theorem. Using similar arguments, it can be shown that:

$$(-1)^{i} y_{2,i} = \begin{bmatrix} \sum_{i=1}^{\infty} (-1)^{i} C_{i} \end{bmatrix} \begin{bmatrix} \sum_{j=1}^{t} (-1)^{j} u_{j} \end{bmatrix} + \begin{bmatrix} \sum_{i=0}^{\infty} (-1)^{i} C_{i} \sum_{j=-i+1}^{0} (-1)^{j} u_{j} \end{bmatrix}$$

$$- \begin{bmatrix} \sum_{i=0}^{\infty} (-1)^{i} C_{i} \sum_{j=t-i+1}^{t} (-1)^{j} u_{j} \end{bmatrix}.$$
(A.10.2)

From (A.1) for k = 2, we can show that:

$$\begin{split} &N^{-2}\sum_{t=1}^{T}D_{st}\,y_{2,t-1}^{2} = C(-1)^{2}\,N^{-2}\sum_{t=1}^{T}D_{st}\!\left[\!\sum_{j=1}^{t-1}\left(-1\right)^{j}u_{j}\!\right]^{2} + o_{p}(1)\\ &= C(-1)^{2}\,N^{-2}\sum_{n=1}^{N}\,w_{2,n-1}^{2} + o_{p}(1). \end{split}$$

Using (A.5) for k = 2, the relation (A.8.2) can be obtained. When $z_{2t}^0 = (1 + B^2) y_{3,t}$ has a moving average representation $Z_{2t}^0 = C(B)u_t$, we can rewrite $y_{3,t}$ as [see Lee (1992, p. 34)]

$$y_{3,i} = C_R \left[C_i \sin(\frac{\pi}{2}t) - S_i \cos(\frac{\pi}{2}t) \right] - C_1 \left[C_i \sin(\frac{\pi}{2}t) + S_i \sin(\frac{\pi}{2}t) \right] + o_p(T^{1/2})$$
(A.10.3)

where $C = \sum_{i=1}^{t-1} \cos(\frac{\pi}{2}t)$

where
$$C_1 = \sum_{j=1}^{t-1} \cos(\frac{\pi}{2}j) u_j$$
 and $S_1 = \sum_{j=1}^{t-1} \sin(\frac{\pi}{2}j) u_j$

Using (A.10.3), we can write:

$$\begin{split} &N^{-2} \sum_{t=1}^{T} D_{st} y_{3,t-1}^{2} = N^{-2} \sum_{t=1}^{T} D_{st} \{ C_{R}^{2} [C_{t}^{2} (\sin \frac{\pi}{2} t)^{2} + S_{t}^{2} \cos(\frac{\pi}{2} t)^{2}] + C_{1}^{2} [C_{t}^{2} \cos(\frac{\pi}{2} t)^{2}] \\ &+ S_{t}^{2} \sin(\frac{\pi}{2} t)^{2}] + C_{R} C_{1} [C_{t} S_{t} (\cos \frac{\pi}{2} t)^{2} - C_{t} S_{t} (\sin \frac{\pi}{2} t)^{2}]\} + o_{p}(1) \\ &= [\sin(\frac{\pi}{2} s)^{2}] N^{-2} \sum_{n=1}^{N} [C_{R}^{2} w_{4,n}^{2} + C_{1}^{2} w_{3,n}^{2} - C_{R} C_{1} w_{3,n} w_{4,n}] \\ &+ [\cos(\frac{\pi}{2} s)]^{2} N^{-2} \sum_{n=1}^{N} [C_{R}^{2} w_{3,n}^{2} + C_{1}^{2} w_{4,n}^{2} + C_{R} C_{1} w_{3,n} w_{4,n}] + o_{p}(1). \end{split}$$

Using (A.1) and (A.5) for k = 3.4, the relation (A.8.3) can be obtained for i = 1. A similar expression can be derived for $N^{-2} \sum_{t=1}^{T} D_{st} y_{3,t-2}^2$, which leads to the result in (A.8.4). Similarly, we can write:

$$\begin{split} &N^{-2}\sum_{t=1}^{T}D_{st}y_{3,t-1}y_{3,t-2}=N^{-2}\sum_{t=1}^{T}D_{st}\{C_{R}^{2}|S_{t}C_{t-1}(\cos\frac{\pi}{2}t)^{2}-C_{t}S_{t-1}(\sin\frac{\pi}{2}t)^{2}\}\\ &+C_{1}^{2}|S_{t}C_{t-1}(\sin\frac{\pi}{2}t)^{2}-C_{t}S_{t-1}(\cos\frac{\pi}{2}t)^{2}]+C_{R}C_{1}|C_{t}C_{t-1}(\sin\frac{\pi}{2}t)^{2}-S_{t}S_{t-1}(\cos\frac{\pi}{2}t)^{2}]\\ &+C_{R}C_{1}|C_{t}C_{t-1}(\cos\frac{\pi}{2}t)^{2}-S_{t}S_{t-1}(\sin\frac{\pi}{2}t)^{2}]+o_{p}(1). \end{split}$$

When S is an even number, the above expression reduces to:

$$N^{-2} \sum_{t=1}^{T} D_{st} [C_R^2 S_t C_{t-1} - C_1^2 C_t S_{t-1} + C_R C_t (C_t C_{t-1} - S_t S_{t-1})].$$

Combining (A.1) and (A.5), the relation (A.8.4) follows from the continuous mapping theorem. The same argument applies to the case when S is an odd number. Note that while $N^{-2}\sum_{t=1}^{T}D_{st}y_{3,t-1}y_{3,t-2}$ converges to a nondegenerate asymptotic distribution in (A.8.4), the two series $y_{3,t-1}$ and $y_{3,t-2}$ are asymptotically uncorrelated in the sense that $\sum_{s=1}^{S}\left[N^{-2}\sum_{t=1}^{T}D_{st}y_{3,t-1}y_{3,t-2}\right]=op(1).$ This property is useful in deriving the asymptotic distribution (A.11.3) below.

(ii) Using (A.1) and (A.10), we obtain:

$$\begin{split} N^{-1} \sum_{t=1}^{T} D_{st} y_{1,t-1} u_{t} &= C(1) N^{-1} \sum_{n=1}^{N} w_{1,n-1} e_{1,n}(s) + o_{p}(1) \\ N^{-1} \sum_{t=1}^{T} D_{st}(-y_{2,t-1} u_{t}) &= N^{-1} \sum_{t=1}^{T} D_{st}(-1)^{t-1} y_{2,t-1}(-1)^{t} u_{t} \\ &= C(-1) N^{-1} \sum_{n=1}^{N} w_{2,n-1} e_{2,n}(s) + o_{p}(1) \end{split}$$

$$\begin{split} N^{-1} \sum_{t=1}^{T} D_{st}(-y_{3,t-1-i} u_t) &= N^{-1} \sum_{n=1}^{N} D_{st}\{-C_R \{C_{t-i} \sin \frac{\pi}{2}(t-i) - S_{t-i} \cos \frac{\pi}{2}(t-i)\} \\ &+ C_1 [C_{t-i} \cos \frac{\pi}{2}(t-i) + S_{t-i} \sin \frac{\pi}{2}(t-i)]\} u_t + o_p(1). \end{split}$$

Noting that $u_t = (-1)^{(t-1)/2} \cos(\frac{\pi}{2}t) u_t + (-1)^{(t-2)/2} \sin(\frac{\pi}{2}t) u_t$, we can write:

$$\begin{split} &N^{-1}\sum_{t=1}^{T}D_{\mathbf{s}t}(-y_{3,t-2}u_{t}) = N^{-1}\sum_{t=1}^{T}D_{\mathbf{s}t}\{(-C_{R}C_{t-1} + C_{I}S_{t-1}) \left[\cos(\frac{\pi}{2}t)\right]^{2}u_{t}(-1)^{(t-1)/2} \\ &+ (C_{R}S_{t-1} + C_{I}C_{t-1}) \left[\sin(\frac{\pi}{2}t)\right]^{2}u_{t}(-1)^{(t-2)/2}\} + o_{p}(1). \end{split}$$

A similar expression can be derived for $N^{-1}\sum_{t=1}^{T}D_{st}(-y_{3,t-1}u_t)$. Combining (A.1) and (A.5), the relations (A.9) can be obtained by using the continuous mapping theorem.

Proof of Theorem 2.1.

(i) Using standard arguments, it can be shown that:

$$W^{R}(\phi) = \sum_{s=1}^{S} (\hat{\alpha}_{s} - \phi)^{2} / \hat{\sigma}^{2} \left[\sum_{t=1}^{T} D_{st} X_{t} X_{t}^{T} \right]^{11}$$

$$= \sum_{s=1}^{S} \left[\sum_{t=1}^{T} D_{st} y_{t-1} u_{t}^{T} \right]^{2} / \hat{\sigma}^{2} \left[\sum_{t=1}^{T} D_{st} y_{t-1}^{2} \right] + o_{p}(1).$$

For the zero frequency case where the null hypothesis is that $H_0^R(1)$: $\alpha_s = 1$ for all s = 1, ..., S, the relations (A.8.1) and (A.9.1) can be used to derive

$$\psi_{S}^{R}(1) = \sum_{s=1}^{S} \left[\int_{0}^{1} G_{1}(r) dB_{1s}(r) \right]^{2} / \left[\int_{0}^{1} G_{1}(r)^{2} dr \right]. \tag{A.11.1}$$

Similarly, for testing $H_0^R(-1)$: $\alpha_s = -1$ for all s, the relations (A.8.2) and (A.9.2) can be used to show:

$$\psi_{S}^{R}(-1) = \sum_{s=1}^{S} \left[\int_{0}^{1} G_{2}(r) dB_{2s}(r) \right]^{2} / \left[\int_{0}^{1} G_{2}(r)^{2} dr \right].$$
(A.11.2)

Noting that $G_1(r)$ and $G_2(r)$ are independent and $B_{2s}(r) = (-1)^s B_{1s}(r)$, it follows that $\psi_S^R(1)$ and $\psi_S^R(-1)$ have the same distribution denoted ψ_S^R . Thus, we can use the same critical values when we are interested in testing for real unit roots, either - 1 or 1.

(ii) To prove $\psi_S^C(s)$ for complex unit roots, we first consider the test statistics under $H_0^C(0)$: $\gamma_{1s} = 0$, $\gamma_{2s} = 1$ for all s = 1, ..., S. In this case, the Wald statistic can be written as:

$$\begin{split} \mathbf{W}_{S}^{C}(0) &= \sum_{s=1}^{S} (\hat{\gamma}_{1s}, \hat{\gamma}_{2j} - 1) \left\{ \begin{bmatrix} \mathbf{T} \\ \sum_{t=1}^{T} \mathbf{D}_{st} \mathbf{X}_{3t} \mathbf{X}_{3t}^{T} \end{bmatrix}^{-1} \right\}_{1:2,1:2} (\hat{\gamma}_{1s}, \hat{\gamma}_{2s} - 1)^{r} / \hat{\sigma}^{2} \\ &= \sum_{s=1}^{S} \begin{bmatrix} \mathbf{T} \\ \sum_{t=1}^{T} \mathbf{D}_{st} (\mathbf{y}_{t-1} \mathbf{u}_{t}, \mathbf{y}_{t-2} \mathbf{u}_{t}) \end{bmatrix} \left\{ \begin{bmatrix} \mathbf{T} \\ \sum_{t=1}^{T} \mathbf{D}_{st} \mathbf{X}_{3t} \mathbf{X}_{3t}^{T} \end{bmatrix}^{-1} \right\}_{1:2,1:2} \\ &\left[\mathbf{T} \\ \sum_{t=1}^{T} \mathbf{D}_{st} (\mathbf{y}_{t-1} \mathbf{u}_{t}, \mathbf{y}_{t-2} \mathbf{u}_{t}) \right]^{r} / \hat{\sigma}^{2} + o_{p}(1) \end{split}$$

where
$$X_{3i} = (-y_{i-1} - y_{i-2}, z_{2,i-1}^0, ..., z_{2,i-p+2}^0)^t$$
.

$$= \operatorname{tr} \left\{ \begin{bmatrix} \sum_{i} D_{1t}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \\ \sum_{i} D_{2t}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \\ \vdots \\ \sum_{i} D_{St}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \end{bmatrix} \begin{bmatrix} T \\ \sum_{i=1}^{T} D_{t} \otimes (y_{t-1} y_{t-2})'(y_{t-1} y_{t-2}) \end{bmatrix}^{-1} \times \right.$$

$$\begin{bmatrix} \sum_{i} D_{1t}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \\ \sum_{i} D_{2t}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \\ \vdots \\ \sum_{i} D_{St}(y_{t-1} u_{t}, y_{t-2} u_{t}^{i}) \end{bmatrix} + o_{p}(1)$$

where $D_l = diag(D_{1l}, D_{2l}, ..., D_{Sl})$.

Using the relations (A.8.3) - (A.8.4) and (A.9.3) - (A.9.4), we can show that:

$$W_{S}^{C}(0) \rightarrow tr\{\int_{0}^{1} dW (G_{3}, G_{4}) [\int_{0}^{1} (G_{3}, G_{4})]^{-1} \int_{0}^{1} (G_{3}, G_{4})' dW'\}$$
(A.11.3)

where W(r) is as defined in (A.4.1). The derivation is tedious as the limiting distributions in (A.8.3) - (A.8.4) and (A.9.3) - (A.9.4) depend on the value of S. In the simple case, when $C_R = 1$ and $C_I = 0$, i.e., $(1 + B^2) y_I = u_I$; however, the relation (A.11.3) can be obtained by straightforward application of the results in Lemma A.1 and the continuous mapping theorem.

Noting that $G_3(r) = \sum_{j=1}^{S/2} (-1)^{j-1} W_{2j-1}(r)$ and $G_4(r) = \sum_{j=1}^{S/2} (-1)^j W_{2j}(r)$, it is convenient to rewrite (A.11.3) as:

$$W_S^C(0) \rightarrow \psi_S^C(0) \text{ tr} \{ \int_0^1 (dG) G_{34}, [\int_0^1 G_{34}, G_{34}] \}^{-1} \{ \int_0^1 G_{34}, [dG], \}$$
 (A.12)

where G(r) is an S-dimensional standard Brownian motion, the first four elements of which are $G_{1234} = \left[(\sqrt{5})^{-1} G_1, (\sqrt{5})^{-1} G_2, \sqrt{2}(\sqrt{5})^{-1} G_3, \sqrt{2}(\sqrt{5})^{-1} G_4 \right]$, and $G_{34}(r)$ is a 2 x 1 vector with the third and fourth elements of G(r).

³ G(r) can be obtained from W(r) by multiplying an orthogonal matrix. Its first four columns are: $(\sqrt{5})^{-1}(1, 1, ..., 1)^*, (\sqrt{5})^{-1}(1, 1, ..., 1)^*, \sqrt{2}(\sqrt{5})^{-1}(1, 0, -1, ..., 0)^*$ and $\sqrt{2}(\sqrt{5})^{-1}(0, -1, 0, ..., 1)^*$.

Next, we show that the limiting distributions for testing the unit roots associated with the polynomial $(1 + \phi B + B^2)$ do not depend on the value of $\phi = 2\cos\theta$. When the hypothesis of interest in the regression model (2.3) is given by $H_0^C(\phi)$: $\gamma_{1s} = \phi$. $\gamma_{2s} = 1$ for all s = 1, ..., S, it can be shown that testing $H_0^C(\phi)$ in (2.3) is equivalent to testing whether $\gamma_{1s}^* = 0$ and $\gamma_{2s}^* = 1$ hold in the regression:

$$y_{t} = \gamma_{1t}^{\star}(-y_{t-1}^{\star}) + \gamma_{2t}^{\star}(-y_{t-2}^{\star}) + \sum_{j=1}^{p-2} z_{2,t-j}^{\phi} + u_{t}$$

where $y_{1-1}^* = \sin\theta \ y_{1-1}$. $y_{1-2}^* = y_{1-2} - 2\cos\theta \ y_{1-1}$ and $z_{2,1}^{\phi} = (1 + \phi B + B^2) \ y_1$. Notice first that when $\theta = \frac{\pi}{2}$ the above regression model reduces to (2.3) and, hence, that the hypothesis $H_0^C * : \gamma_{1s}^* = 0, \ \gamma_{2s}^* = 1$ reduces in this case to $H_0^C (0) : \gamma_{1s} = 0, \ \gamma_{2s} = 1$. In general, the hypothesis $H_0^C * : \theta_0 * : \theta_$

Now, consider:

$$\begin{split} W_{S}^{C}(\phi) &= \sum_{s=1}^{S} \left(\hat{\gamma}_{1s}, \hat{\gamma}_{2s} - 1 \right) \left\{ \left[\sum_{t=1}^{T} D_{st} \times_{\phi_{t}} X_{\phi_{t}}^{*} \right]^{-1} \right\}_{1:2,1:2} \left(\hat{\gamma}_{1s} - \phi, \hat{\gamma}_{2s} - 1 \right) / \hat{\sigma}^{2} \\ &= \sum_{s=1}^{S} \left(\hat{\gamma}_{1s}^{*}, \hat{\gamma}_{2s}^{*} - 1 \right) \left\{ \left[\sum_{t=1}^{T} D_{st} \times_{\phi_{t}}^{*} X_{\phi_{t}}^{*} \right]^{-1} \right\}_{1:2,1:2} \left(\hat{\gamma}_{1s}^{*}, \hat{\gamma}_{2s}^{*} - 1 \right) / \hat{\sigma}^{2} \\ &= \sum_{s=1}^{S} \left\{ \left[\sum_{t=1}^{T} D_{st} (y_{t-1}^{*}, u_{t}, y_{t-2}^{*} u_{t}) \right] \left[\sum_{t=1}^{T} D_{st} (y_{t-1}^{*}, y_{t-2}^{*})' (y_{t-1}^{*}, y_{t-2}^{*}) \right]^{-1} \times \\ &\left[\sum_{t=1}^{T} D_{st} (y_{t-1}^{*} u_{t}, y_{t-2}^{*} u_{t}) \right] / \hat{\sigma}^{2} + o_{p}(1) \end{split}$$

where $X_{\phi i} = (-y_{i-1}, -y_{i-2}, z_{2,i-1}^{\phi}, z_{2,i-p+2}^{\phi})$ and $X_{\phi i}^* = (-y_{i-1}^*, -y_{i-2}^*, z_{2,i-1}^{\phi}, ..., z_{2,i-p+2}^{\phi})$.

Using the relations:

$$N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-1}^{*} u_{t}) = \sin\theta N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-1} u_{t})$$

$$N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-2}^{*} u_{t}) = N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-2} u_{t}) - 2\cos\theta N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-1} u_{t})$$

$$N^{-2} \sum_{t=1}^{T} D_{st} -y_{t-1}^{*2} = \sin^{2}\theta N^{-2} \sum_{t=1}^{T} D_{st} y_{t-1}^{2}$$

$$N^{-1} \sum_{t=1}^{T} D_{st} y_{t-2}^{*2} = N^{-2} \sum_{t=1}^{T} D_{st} y_{t-2}^{2} + 4\cos^{2}\theta N^{-2} \sum_{t=1}^{T} D_{st} y_{t-1}^{2}$$

$$- 4\cos\theta N^{-2} \sum_{t=1}^{T} D_{st} y_{t-1}^{*2}$$

it can be shown that:

$$\begin{split} & \left[\sum_{t=1}^{T} D_{st}(y_{t-1}^{*} \ u_{t}, y_{t-2}^{*} \ u_{t}) \right] \left[\sum_{t=1}^{T} D_{st}(y_{t-1}^{*}, y_{t-2}^{*})^{*} (y_{t-1}^{*}, y_{t-2}^{*})^{*} (y_{t-1}^{*}, y_{t-2}^{*}) \right]^{-1} \left[\sum_{t=1}^{T} D_{st}(y_{t-1}^{*} \ u_{t}, y_{t-2}^{*})^{*} \right] \\ & = \left[\sum_{t=1}^{T} D_{st}(y_{t-1} \ u_{t}, y_{t-2} \ u_{t}) \right] \left[\sum_{t=1}^{T} D_{st}(y_{t-1}, y_{t-2})^{*} (y_{t-1}, y_{t-2}) \right]^{-1} \left[\sum_{t=1}^{T} D_{st}(y_{t-1} \ u_{t}, y_{t-2} \ u_{t})^{*} \right]. \end{split}$$

Therefore, we have:

$$W_S^C(\phi) \rightarrow \psi_S^C = \text{tr} \{ \int_0^1 dG \ G_{34}^* [\int_0^1 G_{34} \ G_{34}^*]^{-1} \ \int_0^1 G_{34} \ dG' \},$$

which is independent of the value of ϕ .

To prove Theorem 2.2, we will use the results in the following lemma.

Lemma A.2. As $T \rightarrow \infty$ (and hence $N \rightarrow \infty$), we have:

(i)
$$N^{-1/2} \sum_{t=1}^{T} D_{st} u_t - \sigma B_{1s}(1)$$
 (A.13.1)

$$N^{-1/2} \sum_{i=1}^{T} D_{si}(-1)^{i} u_{i} \rightarrow \sigma B_{2s}(1)$$
(A.13.2)

$$N^{-1/2} \sum_{t=1}^{T} D_{st} \sin(\frac{\pi}{2}t) u_t \rightarrow \sigma B_{3s}(1)$$
 (A.13.3)

$$N^{-1/2} \sum_{t=1}^{T} D_{st} \cos(\frac{\pi}{2}t) u_{t} - \sigma B_{4s}(1)$$
 (A.13.4)

(ii)
$$N^{-3/2} \sum_{t=1}^{T} D_{st} y_{1,t-1} - C(1) \sigma \int_{0}^{1} G_{1}(r) dr$$
 (A.14.1)

$$N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{2,t-1}) \rightarrow (-1)^{s} C(-1) \sigma \int_{0}^{1} G_{2}(r) dr$$
 (A.14.2)

$$N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{3,t-1}) \rightarrow \cos(\frac{\pi}{2}s) \ \sigma \ [C_R \]_0^1 \ G_3(r) \ dr + C_l \]_0^1 \ G_4(r) \ dr$$

$$-\sin(\frac{\pi}{2}s) \sigma [C_R \int_0^1 G_4(r) dr - C_1 \int_0^1 G_3(r) dr]$$
 (A.14.3)

$$N^{-3/2} \sum_{i=1}^{T} D_{si}(-y_{3,i-2}) \rightarrow \sin(\frac{\pi}{2}s) \ \sigma \ [C_R \ \int_0^1 G_3(r) \ dr + C_1 \ \int_0^1 G_4(r) \ dr$$

$$-\cos(\frac{\pi}{2}s) \sigma \left[C_{R} \int_{0}^{1} G_{4}(r) dr - C_{1} \int_{0}^{1} G_{3}(r) dr\right]$$
 (A.14.4)

(iii)
$$N^{-5/2} \sum_{t=1}^{T} D_{st} n y_{1,t-1} \rightarrow C(1) \sigma \int_{0}^{1} r G_{1}(r) dr$$
 (A.15.1)

$$N^{-5/2} \sum_{t=1}^{T} D_{st} n (-y_{t-1}) \rightarrow (-1)^{s} C(-1) \sigma \int_{0}^{1} r G_{2}(r) dr$$
 (A.15.2)

(iv)
$$N^{-3/2} \sum_{t=1}^{T} D_{st} n u_t \rightarrow \sigma[B_{1s}(1) - \int_0^1 B_{1s}(r) dr]$$
 (A.16.1)

$$N^{-3/2} \sum_{t=1}^{T} D_{st} (-1)^{t} u_{t} \rightarrow \sigma[B_{2s}(1) - \int_{0}^{1} B_{2s}(r) dr]$$
(A.16.2)

Proof.

- (i) The relations in (A.13) follow immediately from (A.1) and (A.4).
- (ii) Using (A.1) and (A.10), it can be shown that:

$$\begin{split} &N^{-3/2}\sum_{t=1}^{T}D_{st}y_{1,t-1} = C(1)N^{-3/2}\sum_{t=1}^{T}D_{st}\begin{bmatrix}\sum_{j=1}^{t-1}u_{j}\\ \sum_{j=1}^{t}u_{j}\end{bmatrix} + o_{p}(1)\\ &= C(1)N^{-3/2}\sum_{n=1}^{N}w_{1,n-1} + o_{p}(1). \end{split}$$

To show (A.14.2), define $w_{2,n-1}(s) = (-1)^s \sum_{j=1}^{(n-1)} (-1)^j u_j$. Then, we have:

$$w_{2,n-1}(s) = (-1)^{s} \left[w_{2,n-1} + \sum_{j=1}^{S} (-1)^{j} u_{(n-1)S+j} \right].$$

Thus, we obtain:

$$N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{2,t-1}) = C(-1) N^{-3/2} \sum_{t=1}^{T} D_{st}(-1) \begin{bmatrix} t-1 \\ \sum \\ j=1 \end{bmatrix} (-1)^{j} u_{j} + o_{p}(1)$$

$$= C(-1) N^{-3/2} \sum_{n=1}^{N} (-1)^{n} w_{2,n-1(s-1)} + o_{p}(1)$$

$$= C(-1) N^{-3/2} \sum_{n=1}^{N} (-1)^{s} w_{2,n-1} + o_{p}(1).$$

The relations (A.14.3) and (A.14.4) can similarly be obtained from (A.10.3) and the continuous mapping theorem. That is,

$$N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{3,t-1}) \begin{cases} = (-1)^{(s+1)/2} N^{-3/2} \sum_{n=1}^{N} (C_R w_{4,n} - C_1 w_{3,n}) + o_p(1), \text{ for so odd} \\ = (-1)^{s/2} N^{-3/2} \sum_{n=1}^{N} (C_R w_{3,n} - C_1 w_{4,n}) + o_p(1), \text{ for seven} \end{cases}$$

$$N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{3,t-2}) \begin{cases} = (-1)^{(s-1)/2} N^{-3/2} \sum_{n=1}^{N} (C_R w_{3,n} - C_1 w_{4,n}) + o_p(1), \text{ for sodd} \\ = (-1)^{(s/2)/2} N^{-3/2} \sum_{n=1}^{N} (C_R w_{4,n} - C_1 w_{3,n}) + o_p(1), \text{ for seven.} \end{cases}$$

(iii) Using similar arguments, one can show that:

$$N^{-5/2} \sum_{t=1}^{T} D_{st} n y_{1,t-1} = C(1) N^{-3/2} \sum_{n=1}^{N} {n \choose N} w_{1,n-1} + o_{p}(1)$$

$$N^{-5/2} \sum_{t=1}^{T} D_{st} n (-y_{2,t-1}) = (-1)^{5} C(-1) N^{-3/2} \sum_{n=1}^{N} {n \choose N} w_{2,n-1} + o_{p}(1).$$

The relations in (A.15) follow from (A.2), (A.4) and Phillips and Perron (1988). Similar expressions can be obtained for $y_{3,t}$, which are suppressed here, as they are not explicitly used in the proof of Theorem 2.2.

(iv) Similarly, one can also show that

$$N^{-3/2} \sum_{t=1}^{T} D_{st} n u_{t} = N^{-1/2} \sum_{n=1}^{N} \left[\frac{n}{N} \right] z_{1n(s)} \rightarrow o(B_{1s}(1) - \int_{0}^{1} B_{1s}(r) dr).$$

The other result given in the lemma follows by similar arguments.

Proof of Theorem 2.2.

(i) We follow the steps of the proof of Theorem 2.1. It can be shown that for $\phi = 1$:

$$W_{S\mu}^{R}(\phi) = \sum_{s=1}^{S} \left[\sum_{t=1}^{T} D_{st}(y_{t-1} - \bar{y}_{s}) (u_{t} - \bar{u}_{s}) \right]^{2} / \sigma^{2} \left[\sum_{t=1}^{T} D_{st}(y_{t-1} - \bar{y}_{s})^{2} \right] + o_{p}(1)$$
(A.17)

where
$$\overline{y}_s = N^{-1} \sum_{t=1}^{T} D_{st} y_{t-1}$$
, $\overline{u}_s = N^{-1} \sum_{t=1}^{T} D_{st} u_t$.

Using standard arguments, it is easy to rewrite (A.17) as:

$$\begin{split} W_{S\mu}^{R}(\phi) &= \sum_{s=1}^{S} \left[\left[N^{-1} \sum_{t=1}^{T} D_{st} y_{t-1} u_{t} - \left[N^{-3/2} \sum_{t=1}^{T} D_{st} y_{t-1} \right] \left[N^{-1/2} \sum_{t=1}^{T} D_{st} u_{t} \right] \right] \\ &\left[N^{-2} \sum_{t=1}^{T} D_{st} y_{t-1}^{2} - \left[N^{-3/2} \sum_{t=1}^{T} D_{st} y_{t-1} \right]^{2} \right]^{-1} \right] + o_{p}(1) \end{split} \tag{A.18}$$

Combining the results in Lemmas A.1 and A.2, i.e., (A.8.1), (A.13.1), (A.14.1), we obtain the formula for $\psi_{SII}^{R}(\phi)$:

$$\psi_{S\mu}^{R}(\phi) = \sum_{s=1}^{S} \left[\int_{0}^{1} G_{1}(r) dB_{1s}(r) - \int_{0}^{1} G_{1}(r) drB_{1s}(1) \right]^{2} / \left[\int_{0}^{1} G_{1}(r)^{2} dr - \left(\int_{0}^{1} G_{1}(r) dr \right)^{2} \right]. \tag{A.19.1}$$

As for $W_{SH}^{R}(\phi)$ with $\phi = -1$, we can use similar arguments to obtain:

$$\begin{split} W_{S\mu}^{R}(-1) &= \sum_{s=1}^{S} \left\{ N^{-1} \sum_{t=1}^{T} D_{st}(-y_{t-1} u_{t}) - \left[N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{t-1}) \right] \left[N^{-1/2} \sum_{t=1}^{T} D_{st} u_{t} \right] \right\} \\ \sigma^{-2} \left\{ N^{-2} \sum_{t=1}^{T} D_{st} y_{t-1}^{2} - \left[N^{-3/2} \sum_{t=1}^{T} D_{st}(-y_{t-1}) \right]^{2} \right\}^{-1} + o_{p}(1). \end{split}$$

Noting that $N^{-1/2}$ $\sum_{t=1}^{T}$ D_{st} $u_t = (-1)^s N^{-1/2}$ $\sum_{t=1}^{T}$ $D_{st}(-1)$ u_t , the formula for $\psi_{S\mu}^R$ can then be obtained as:

$$\psi_{S\mu}^{R}(-1) = \sum_{s=1}^{S} \left[\int_{0}^{1} G_{2}(r) dB_{2s}(r) - \int_{0}^{1} G_{2}(r) dr B_{2s}(1) \right]^{2} / \left[\int_{0}^{1} G_{2}(r)^{2} dr - \left(\int_{0}^{1} G_{2}(r) dr \right)^{2} \right]$$
(A.19.2)

As for $W_{S\mu}^{C}(\phi)$, we use arguments similar to (A.18) where y_{t-1} , y_{t-2} and u_{t} in the Wald statistic need to be replaced by their "demeaned" counterparts, i.e., $(y_{t-1} - \overline{y}_{-1,s})$, $(y_{t-2} - \overline{y}_{-2,s})$ and $(u_{t} - \overline{u}_{s})$, respectively. The results in Lemma A.1 and A.2 can be used to obtain:

$$W_{S\mu}^{C} \rightarrow \psi_{S\mu}^{C} = \text{tr} \left\{ \int_{0}^{1} dG \, F_{34}^{*} \left[\int_{0}^{1} F_{34} \, F_{34}^{*} \right]^{-1} \int_{0}^{1} F_{34} \, dG^{*} \right\}$$
(A.19.3)

where $F_{34}(r) = G_{34}(r) - \int_0^1 G_{34}(r) dr$ is a 2-dimensional Brownian motion, which is the demeaned counterpart of $G_{34}(r)$.

(ii) As for the test statistics for the regression models with an intercept and a linear time trend, we can show, for instance, that [see, e.g., Phillips and Perron (1998)]

$$W_{S\tau}^{R}(\phi) = \sum_{s=1}^{S} M_{s}(\hat{\alpha}_{s} - 1)^{2} / \hat{\sigma}^{2}[N^{2}(N^{2} - 1) / 12] + o_{p}(1)$$

where

$$\begin{split} \widehat{\alpha}_{s} - 1 &= M_{s}^{-1} \left\{ [N(N+1)/2] \sum_{t=1}^{T} D_{st} \, n \, y_{t-1} \sum_{t=1}^{T} D_{st} \, u_{t} \right. \\ &- [N(N+1)(2N+1)/6] \sum_{t=1}^{T} D_{st} \, y_{t-1} \sum_{t=1}^{T} D_{st} \, u_{t} \\ &- N \sum_{t=1}^{T} D_{st} \, n \, y_{t-1} \sum_{t=1}^{T} D_{st} \, n \, u_{t} + [N(N+1)/2] \sum_{t=1}^{T} D_{st} \, y_{t-1} \sum_{t=1}^{T} D_{st} \, n \, u_{t} \\ &+ [N^{2}(N^{2}-1)/12] \sum_{t=1}^{T} D_{st} \, y_{t-1} \, u_{t} \right\} + o_{p}(1) \\ &M_{s} = [N^{2}(N^{2}-1)/12] \sum_{t=1}^{T} D_{st} \, y_{t-1} - N \left[\sum_{t=1}^{T} D_{st} \, n \, y_{t-1} \right]^{2} \\ &+ N(N+1) \sum_{t=1}^{T} D_{st} \, n \, y_{t-1} \sum_{t=1}^{T} D_{st} \, y_{t-1} - [N(N+1)(2N+1)/6] \left[\sum_{t=1}^{T} D_{st} \, n \, y_{t-1} \right]^{2} \end{split}$$

Combining the results for $y_{1,t-1}$ in Lemmas A.1 and A.2, we obtain:

$$W_{S\tau}^{R}(\phi) \rightarrow \psi_{S\tau}^{R} = \sum_{s=1}^{S} A_{s}^{2} / D$$
 (A.20.1)

where

$$\begin{split} A_s &= 6 \ B_{1s}(1) \int_0^1 r \ G_1(r) \ dr - 4 \ B_{1s}(1) \int_0^1 G_1(r) \ dr \\ &- 12[B_{1s}(1) - \int_0^1 B_{1s}(r) \ dr] \int_0^1 r \ G_1(r) \ dr - \frac{1}{2} \int_0^1 G_1(r) \ dr] + \int_0^1 G_1(r) \ dB_{1s}(r), \\ D &= \int_0^1 G_1(r)^2 \ dr - 12 \left[\int_0^1 r \ G_1(r) \ dr \right]^2 + 12 \int_0^1 G_1(r) \ dr \int_0^1 r \ G_1(r) \ dr \\ &- 4 \left[\int_0^1 G_1(r) \ dr \right]^2 \end{split}$$

The same formula can be obtained for $W_{ST}^R(-1)$ except that $G_1(r)$ and $B_{1s}(r)$ should be replaced by $G_2(r)$ and $B_{2s}(r)$. As mentioned in the proof of Theorem 2.1, $W_{ST}^R(-1)$ have the same distribution, and the same critical values can be used to test for real unit roots ± 1 . As for the limiting distribution of $W_{ST}^C(\phi)$, it should be noted first that A_s and D in (A.20.1) can be rewritten as:

$$A_s = \int_0^1 G_1^*(r) dB_{1s}(r) \text{ and } D = \int_0^1 G_1^*(r)^2 dr$$

where $G_1^*(r)$ is a "detrended" Brownian motion such that

$$G_1^*(r) = G_1(r) - 4 \int_0^1 G_1(t) dt - \frac{3}{2} \int_0^1 t G_1(t) dt + 6r \int_0^1 G_1(t) dt - 2 \int_0^1 t G_1(t) dt \right)$$

Using similar arguments to the derivation of $\psi_{S\mu}^{C}$ in (A.19.3), it can be shown that:

$$\psi_{S\tau}^{C} = \text{tr}\{\int_{0}^{1} dG \, H_{34}^{*} \, [\int_{0}^{1} H_{34} \, H_{34}^{*}]^{-1} \int_{0}^{1} H_{34} \, dG'\}$$
(A.20.2)

where

$$H_{34}(t) = G_{34}(t) - 4 \left[\int_0^1 G_{34}(t) dt - \frac{3}{2} \int_0^1 t G_{34}(t) dt \right] + 6r \left[\int_0^1 G_{34}(t) dt - 2 \int_0^1 t G_{34}(t) dt \right].$$

Using analogous arguments to the proof of Theorem 2.1, it follows that for any arbitrary choice of ϕ such that $|\phi| < 2$:

$$w^C_{s\mu}(\phi) \rightarrow \psi^C_{s\mu}$$

$$w^C_{s\tau}(\phi) \rightarrow \psi^C_{s\tau}$$

Proof of Theorem 3.1.

As in the proof of Theorem 2.1, one can show that:

$$\begin{split} W_{4}^{A} &= \sum_{s=1}^{S} (\hat{\pi}_{1s}, \hat{\pi}_{2s}, \hat{\pi}_{3s}, \hat{\pi}_{4s}) \left\{ \begin{bmatrix} T \\ t=1 \end{bmatrix} D_{st} X_{4t} X_{4t}^{T} \end{bmatrix}^{-1} \right\}_{1:4,1:4} (\hat{\pi}_{1s}, \hat{\pi}_{2s}, \hat{\pi}_{3s}, \hat{\pi}_{4s})^{T} / \hat{\sigma}^{2} \\ &= \sum_{s=1}^{S} \begin{bmatrix} T \\ \sum_{t=1}^{T} D_{st} (y_{1,t-1} u_{t}, y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) \end{bmatrix} \left\{ \begin{bmatrix} T \\ t=1 \end{bmatrix} D_{st} X_{4t} X_{4t}^{T} \end{bmatrix}^{-1} \right\}_{1:4,1:4} \\ &\left[\sum_{t=1}^{T} D_{st} (y_{1,t-1} u_{t}, y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) + o_{p}(1). \end{split}$$

Moreover, according to the proof of Lemma A.1, it follows that:

$$\begin{split} &N^{-2} \sum_{t=1}^{T} D_{st} y_{1,t-1} (-y_{2,t-1}) + (-1)^{S} C(1) C(-1) \sigma^{2} \int_{0}^{1} G_{1}(r) G_{2}(r) dr \\ &N^{-2} \sum_{t=1}^{T} D_{st} y_{1,t-1} (-y_{3,t-1-i}) + \cos[\frac{\pi}{2}(s-i)] C(1) \sigma^{2} \times \\ & [\int_{0}^{1} G_{1}(r) G_{3}(r) dr + C_{1} \int_{0}^{1} G_{1}(r) G_{4}(r) dr] \\ & - \sin[\frac{\pi}{2}(s+i)] C(1) \sigma^{2} [C_{R} \int_{0}^{1} G_{1}(r) G_{4}(r) dr - C_{1} \int_{0}^{1} G_{1}(r) G_{3}(r) dr] \end{split}$$

$$\begin{split} N^{-2} \sum_{t=1}^{T} D_{st} y_{2,t-1} y_{3,t-1:i} &\rightarrow (-1)^{s} \cos[\frac{\pi}{2}(s-i)] C(-1) \sigma^{2} \times \\ [C_{R} \int_{0}^{1} G_{2}(r) G_{3}(r) dr + C_{1} \int_{0}^{1} G_{2}(r) G_{4}(r) dr] \\ &- (-1)^{s} \sin[\frac{\pi}{2}(s-i)] C(-1) \sigma^{2} [C_{R} \int_{0}^{1} G_{2}(r) G_{4}(r) dr - C_{1} \int_{0}^{1} G_{2}(r) G_{3}(r) dr]. \end{split}$$

Note that while $N^{-2} \sum_{t=1}^{T} D_{st} y_{k,t}, y_{j,t}$ (k, j = 1, 2, 3, k \neq j) have a nondegenerating asymptotic distribution for each season, they are uncorrelated asymptotically so that:

$$T^{-2} \sum_{t=1}^{T} y_{k,t} y_{j,t} = \sum_{s=1}^{S} \left[N^{-2} \sum_{t=1}^{T} D_{st} y_{k,t} y_{j,t} \right] = O_{p}(1).$$

Using this property, it can be shown that:

$$W_{4}^{A} = tr \begin{cases} \begin{bmatrix} T \\ \sum_{t=1}^{T} D_{1t}(y_{1,t-1} u_{t}, y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) \\ \vdots \\ T \\ \sum_{t=1}^{T} D_{4t}(y_{1,t-1} u_{t}, y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) \end{bmatrix} \times \\ \begin{bmatrix} T \\ \sum_{t=1}^{T} D_{4t}(y_{1,t-1}, y_{2,t-1}, y_{3,t-1}, y_{4,t-1}), (y_{1,t-1}, y_{2,t-1}, y_{3,t-2}, y_{3,t-2}) \end{bmatrix}^{-1} \times \\ \begin{bmatrix} T \\ \sum_{t=1}^{T} D_{1t}(y_{1,t-1} u_{t}, \dots, y_{3,t-1} u_{t}) \\ \vdots \\ T \\ \sum_{t=1}^{T} D_{4t}(y_{1,t-1} u_{t}, \dots, y_{3,t-2} u_{t}) \end{bmatrix}^{-1} \\ \end{bmatrix} / \sigma^{2} + o_{p}(1).$$

The relations in Lemmas A.1 and A.2 can then be used to obtain:

$$W_4^A \rightarrow tr\{\int_0^1 dW \ G'[\int_0^1 G \ G']^{-1} \int_0^1 G \ dW'\}$$

where G(r) is a 4-dimensional standard Brownian motion such that $G = (1/2 G_1, 1/2 G_2, 1/\sqrt{2} G_3, 1/\sqrt{2} G_4)$. Then as in (A.12), the above expression can be rewritten as:

$$W_4^A \rightarrow \psi_4^A = \text{tr}\{\int_0^1 (dG) \ G'[\int_0^1 G \ G']^{-1} \int_0^1 G \ (dG)'\}.$$

Note that the Wald statistic W_4^A for the hypothesis that $\pi_{1s} = \pi_{2s} = \pi_{3s} = \pi_{4s} = 0$ for all s = 1, ..., 4 has the same asymptotic distribution as the Johanson's test statistic for cointegration with (n - r) = 4. See Table 1 in Johanson (1988, p. 239).

As for the Wald statistic W_{4}^{S} , we can first show that:

$$W_{4}^{S} = \sum_{j=1}^{S} (\hat{\pi}_{2s} \hat{\pi}_{3s} \hat{\pi}_{4s}) \left\{ \left[\sum_{t=1}^{T} D_{st} X_{4t} X_{4t}^{\top} \right]^{-1} \right\}_{2:4,2;4} (\hat{\pi}_{2s} \hat{\pi}_{3s} \hat{\pi}_{4s})^{*} / \hat{\sigma}^{2}$$

$$= \sum_{S=1}^{S} \left[\sum_{t=1}^{T} D_{st} (y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) \right] \left\{ \left[\sum_{t=1}^{T} D_{st} X_{4t} X_{4t}^{\top} \right]^{-1} \right\}_{2:4,2:4}$$

$$\left[\sum_{t=1}^{T} D_{st} (y_{2,t-1} u_{t}, y_{3,t-1} u_{t}, y_{3,t-2} u_{t}) \right] / \sigma^{2} + o_{p}(1).$$

Then, it can be shown that:

$$W_4^S \rightarrow tr\{\int_0^1 (dW) G_{234}^* \{\int_0^1 G_{234} G_{234}^*\}^{-1} \int_0^1 G_{234}^* (dW)^*\}$$

where $G_{234}(r) = (1/2 G_2(r), 1/\sqrt{2} G_3(r), 1/\sqrt{2} G_4(r))'$. By multiplying an orthogonal matrix to W (see footnote 1 for details), we can show that:

$$W_4^S \rightarrow \psi_4^S = \text{tr} \{ \int_0^1 (dG) G_{234}^{'} [\int_0^1 G_{234} G_{234}^{'}]^{-1} \int_0^1 G_{234}^{'} (dG)' \}.$$

As for the test statistics for the regression models which contain deterministic terms (intercept and time trend), we can use developments similar to the proof of Theorem 2.2 except that the Brownian motion process G(r) needs to be replaced by its "demeaned" and "detrended" versions, respectively. That is,

$$W_{4\mu}^{A} \rightarrow \psi_{4\mu}^{A} = tr\{\int_{0}^{1} (dG) F [\int_{0}^{1} F F]^{-1} \int_{0}^{1} F (dG)'\}$$

$$W_{4\tau}^S \to \psi_{4\tau}^S = \text{tr}\{\int_0^1 (\mathrm{d}G) \; H'[\int_0^1 H \; H]^{-1} \; \int_0^1 H (\mathrm{d}G)'\}$$

where

$$F(r) = G(r) - \int_0^1 G(r) dr$$

and

$$H(r) = F(r) - 12(r - \frac{1}{2}) \int_0^1 (t - \frac{1}{2}) F(t) dt.$$

It should be noted that $W_{4\mu}^A$ has the same asymptotic distribution as the LR statistic for cointegration in Johanson and Juselius (1990, Table A.2), and that $W_{4\tau}^A$ has the same distribution as $TR_{\tau}(n-r)$ statistic in Perron and Campbell (1993, p. 787) with (n-r)=4.

Similar expressions can be obtained for $W^S_{4\mu}$ and $W^S_{4\iota}$, namely:

$$W_{4\mu}^S \to \psi_{4\mu}^S = \text{tr}\{\int_0^1 (\mathrm{d}G) \; F_{234}^* \; [\int_0^1 \; F_{234} \; F_{234}^*]^{-1} \; \int_0^1 \; F_{234}^* (\mathrm{d}G)^*\}$$

$$W_{4\tau}^S \to \psi_{4\tau}^S = \text{tr}\{\int_0^1 (\mathrm{d}G) \ H_{234}^* \left[\int_0^1 H_{234} \ H_{234}^*\right]^{-1} \int_0^1 H_{234}(\mathrm{d}G)^*\}.$$

To conclude, we turn our attention to the monthly regression models. To do so, first, we define an appropriate set of filtered series:

$$y_{1t} = (1 + B + B^2 + B^3 + B^4 + B^5 + B^6 + B^7 + B^8 + B^9 + B^{10} + B^{11})_{x_{t}}$$

$$y_{2i} = -(1 - B + B^2 - B^3 + B^4 - B^5 + B^6 - B^7 + B^8 - B^9 + B^{10} - B^{11})x_{11}$$

$$y_{3t} = -(B - B^3 + B^5 - B^7 + B^9 - B^{11})x_t$$

$$y_{4i} = -(1 - B^2 + B^4 - B^6 + B^8 - B^{10})x_{i}$$

$$y_{5i} = -\frac{1}{2}(1 + B - 2B^{2} + B^{3} + B^{4} - 2B^{5} + B^{6} + B^{7} - 2B^{8} + B^{9} + B^{10} - 2B^{11})x_{i}.$$

$$y_{6i} = \frac{\sqrt{3}}{2}(1 - B + B^{3} - B^{4} + B^{6} - B^{7} + B^{9} - B^{10})x_{i}.$$

$$y_{7i} = \frac{1}{2}(1 - B - 2B^{2} - B^{3} + B^{4} + 2B^{5} + B^{6} - B^{7} - 2B^{8} - B^{9} + B^{10} + 2B^{11})x_{i}.$$

$$y_{8i} = \frac{\sqrt{3}}{2}(1 + B - B^{3} - B^{4} + B^{6} + B^{7} - B^{9} - B^{10})x_{i}.$$

$$y_{9i} = -\frac{1}{2}(\sqrt{3} - B + B^{3} - \sqrt{3}B^{4} + 2B^{5} - \sqrt{3}B^{6} + B^{7} - B^{9} + \sqrt{3}B^{10} - 2B^{11})x_{i}.$$

$$y_{10i} = \frac{1}{2}(1 - \sqrt{3}B + 2B^{2} - \sqrt{3}B^{3} + B^{4} - B^{6} + \sqrt{3}B^{7} - 2B^{8} + \sqrt{3}B^{9} - B^{10})x_{i}.$$

$$y_{11i} = \frac{1}{2}(\sqrt{3} + B - B^{3} - \sqrt{3}B^{4} - 2B^{5} - \sqrt{3}B^{6} - B^{7} + B^{9} + \sqrt{3}B^{10} + 2B^{11})x_{i}.$$

$$y_{12i} = \frac{1}{2}(1 + \sqrt{3}B + 2B^{2} + \sqrt{3}B^{3} + B^{4} - B^{6} - \sqrt{3}B^{7} - 2B^{8} - \sqrt{3}B^{9} - B^{10})x_{i}.$$

$$z_{1}^{12} = (1 - B^{12})x_{i}.$$

Regressions similar to (3.1) through (3.3), can then be defined as:

$$z_{t}^{12} = \sum_{i=1}^{12} \pi_{it} y_{it-1} + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{12} + \mu_{t}$$
(A.21)

$$z_{t}^{12} = \sum_{i=1}^{12} \pi_{it} y_{it-1} + \mu_{t} + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{12} + \mu_{t}$$
(A.22)

$$z_{t}^{12} = \sum_{i=1}^{12} \pi_{it} y_{it-1} + \mu_{t} + \beta_{t} (n - N/2) + \sum_{j=1}^{p-3} \theta_{jt} z_{t-j}^{12} + \mu_{t}$$
(A.23)

The hypotheses of interest, test statistics and distributions drawn from these regressions appear in Table 3.1. The hypotheses $H_0^A(12)$ and $H_0^S(12)$ are analogous to the quarterly $H_0^A(4)$ and $H_0^S(4)$ appearing in the main body of the text.
